Convergence and differentiation of Zernike expansion: application for an analysis of odd-order surfaces

Takao Tanabe, Masato Shibuya, and Kazuhisa Maehara

1 Introduction

New types of aspheric surfaces and their mathematical expressions have been proposed in optical design. In particular, the effectiveness of odd-order surfaces, which are expressed with terms including an odd-integer power of the radius, has begun to be recognized via the designs of viewfinders, microscopes, camera lenses, projection display optics, EUV optical systems, and so on. Since aberration characteristics of odd-order surfaces differ largely from those of conventional aspheric surfaces, it is meaningful and important to analyze the features of odd-order surfaces mathematically.

Shibuya et al. pointed out that not only surface shape but also surface slope should be fully approximated to express an optical surface because the refraction of light is determined by the tangent of the surface. From this viewpoint, by considering Taylor expansion, they proved that no odd-order surfaces can be fully represented by even-order terms and thus deduced that the odd-order surfaces have different aberration characteristics from conventional even-order surfaces. They concluded that this peculiarity of odd-order surfaces leads to effectiveness in optical design. However, they ignored the possibility that a finite number of Zernike polynomials fully approximates odd-order surface shapes and slopes.

To analyze aberration characteristics of aspheric surfaces mathematically, Zernike expansion is the most common tool because each Zernike polynomial corresponds to a specific geometrical aberration. Zernike polynomials were originally introduced by Zernike as the eigenfunctions of a rotationally symmetrical and self-adjoint differential equation on the unit disk. The orthogonality and the $L^2$-completeness of Zernike polynomials are direct consequences of this definition. Another definition was given by Bhatia and Wolf from the viewpoint of symmetry. In this literature, convergence of Zernike expansion is not explicitly discussed, but is regarded as an implicit condition. A mathematician, Szego presented an explicit and strong solution for the convergence problem. That is, uniform convergence is fulfilled for a wide class of orthogonal expansion.

Braat and Janssen gave an example of explicit Zernike expansion coefficients by factorial functions or the gamma function. For derivatives of Zernike polynomials, many researchers such as Nijboer obtained the recurring formulae of derivatives to convert wavefront aberrations into geometrical aberrations. This derivation was based on the three term equalities of Gauss’s hypergeometric function. Janssen discussed the derivative formulae in connection with a Laplace operator. He presented the effectiveness of his method in the calculation and measurement of geometrical aberrations. He also mentioned that this method is applied to solve the Neumann problem of differential equations. By studying the algebraic structure of differential operators on the complex unit disk, Wünsche generalized these discussions and derived a generalized form of orthogonal polynomials in the analogy of quantum theory.

As mentioned above, expansion by orthogonal polynomials and its derivatives have been deeply investigated. However, as far as we know, a concrete formulation for odd-order surfaces cannot be found. In particular, both the convergence of Zernike expansion and the convergence of termwise differentiation of Zernike expansion are not discussed in any literature at all.

The goal of this study is to prove that both shapes and slopes of odd-order surfaces are fairly approximated by finite numbers of Zernike polynomials. To show this, we address the convergence of Zernike expansion and their derivatives specifically for odd-order surfaces. Section defines Zernike polynomials and describes their derivation formulae. We present the expansion coefficients of odd-order surfaces and an estimation of the decreasing speed of Zernike coefficients mainly for odd-order surfaces. In Sec., we originally give a proof of the convergence for Zernike expansion in surface shapes and slopes for odd-order surfaces using the result of Sec. In Sec. we practically...
show the effectiveness of the expansion formula by its numerical estimation. By applying the result to lens design of a Schmidt surface, we demonstrate that both the corrector shape and slope are fully approximated by a finite number of Zernike polynomials.

In addition, the resultant approximation of an odd-order surface is not an example of Taylor expansion, which will be briefly explained in Sec. 2.1. Thus, the result of our method does not contradict the consequences of Ref. 11, which describes the impossibility of Taylor expansion of odd-order surfaces.

To express aspherical surfaces, expansion into power series, Zernike expansion, Qcon polynomials, and so on have been used. The method described in this paper allows us to analyze odd-order surfaces by Zernike polynomials and power series. Expressing odd-order surfaces by Qcon surfaces is our future issue.

2 Definition of Zernike Polynomials and Their Basic Properties

2.1 Definition of Rotationally Symmetrical Zernike Polynomials

Rotationally symmetrical Zernike polynomials $Z_{2n}^0(r)$ are given as

$$ Z_{2n}^0(r) = Q_n(t) = \frac{(-1)^n}{n!} \frac{d^n}{dt^n} r^n (1-t)^n, \quad (1) $$

where $t = r^2$, $r$ is the normalized radial coordinate, and $n$ is a non-negative integer.

This definition of the right-side differential is called the Rodrigues formula. Explicitly, one obtains the first six polynomials as

- $Q_0(t) = 1$,
- $Q_1(t) = 2t - 1$,
- $Q_2(t) = 6t^2 - 6t + 1$,
- $Q_3(t) = 20t^3 - 30t^2 + 12t - 1$,
- $Q_4(t) = 70t^4 - 40t^3 + 90t^2 - 20t + 1$,
- $Q_5(t) = 252t^5 - 630t^4 + 560t^3 - 210t^2 + 30t - 1$. (2)

Their orthogonality is expressed as

$$ \int_0^1 Q_n(t) Q_m(t) dt = \frac{1}{2n+1} \delta_{m,n}, \quad (3) $$

where $\delta_{m,n}$ is Kronecker’s delta.

Since $\{Q_n(t)\}$ is a complete orthogonal set on the unit interval of $[0, 1]$, any $L^2$ function $f(t)$ is expanded by $\{Q_n(t)\}$. Namely,

$$ f(t) = a_0 Q_0(t) + a_1 Q_1(t) + a_2 Q_2(t) + \cdots, \quad (4) $$

where the coefficients are

$$ a_n = (2n + 1) \int_0^1 f(t) Q_n(t) dt. \quad (5) $$

The expansion by orthogonal polynomials such as Eq. (4) is also expressed as a polynomial $f(t) = c_0 + c_1 t + c_2 t^2 + \cdots + c_N t^N$ by taking the terms up to $N$ and rearranging the order of terms by Eq. (2). Although this formal expansion does not give an example of Taylor expansion, this is actually a fair approximation of the original function $f(t)$. (If the expression $f(t) = c_0 + c_1 t + c_2 t^2 + \cdots$ is a Taylor expansion, the coefficients $c_k$ do not depend on the number of terms. However, in this case, the constant term $c_0 = \sum_{k=0}^N (-1)^k a_k$ obviously depends on the number of terms $N$. Hence this is not an example of Taylor expansion.) This fact will be demonstrated in Sec. 3, Eq. (3) using $f(t) = t^{3/2}$ as an example.

2.2 Theoretical Estimation of the Decreasing Speed of Zernike Coefficients

For a generic monomial $f(t) = r^{2n} = r^\alpha (\alpha > 0)$, the coefficients of Eq. (4) are expressed by the gamma function. That is,

$$ a_n = \frac{(2n + 1) \Gamma(\alpha + 1)^2}{\Gamma(\alpha + n + 2) \Gamma(\alpha - n + 1)}. \quad (6) $$

Hence, the expansion becomes

$$ f(t) = r^\alpha \sum_{n=0}^\infty \frac{(2n + 1) \Gamma(\alpha + 1)^2}{\Gamma(\alpha + n + 2) \Gamma(\alpha - n + 1)} Q_n(t). \quad (7) $$

Braat and Janssen gave an equivalent formulation by analytical extension of an even-order term. We present another derivation of this expression by use of the beta function $B(p, q)$. Substituting $f(t) = r^\alpha$ into Eq. (4) and integrating by part,

$$ a_n = (2n + 1) \frac{(-1)^n}{n!} \int_0^1 t^n \frac{d^n}{dt^n} (1-t)^n dt $n! a(\alpha - 1) \cdots (\alpha - n + 1) \int_0^1 t^{n-1} r^\alpha (1-t)^\alpha dt = \frac{2n + 1}{n!} B(\alpha + 1, n + 1) $$

$$ = \frac{2n + 1}{n!} \frac{\Gamma(\alpha + 1) \Gamma(n + 1)}{\Gamma(\alpha + n + 2)}. $$

The last equality is derived by $B(p, q) = \Gamma(p) \Gamma(q)/\Gamma(p + q)$.

In order to evaluate the convergence, we estimate the decreasing speed of $a_n$. For representing an odd-order aspherical surface, let $\alpha$ be a noninteger and $\alpha \geq 1/2$. The minimum $\alpha = 1/2$ corresponds to the first-order surface or the cone. By Euler’s reflection formula $\Gamma(z) \Gamma(1 - z) = \pi/\sin \pi z$,
\[ \Gamma(\alpha - n + 1) = \frac{\sin \pi(n - \alpha)}{\pi} \frac{1}{\Gamma(n - \alpha)}. \] (9)

By the definition of the gamma function of \( \Gamma(z + 1) = z\Gamma(z) \),

\[ \Gamma(\alpha + n + 2) = (\alpha + n + 1)(\alpha + n)\Gamma(n + \alpha). \] (10)

The denominator of Eq. (9) is

\[ \Gamma(\alpha + n + 2)\Gamma(\alpha - n + 1) = \frac{\sin \pi(n - \alpha)}{\pi} \frac{(\alpha + n + 1)}{(\alpha + n)} \Gamma(n + \alpha) \times (\alpha + n + 1)(\alpha + n)(\alpha + n - 1). \] (11)

Since \( \alpha \geq 1/2 \), the inequality \( n + \alpha > n + \alpha - 1 \geq n - \alpha \) holds. Since \( \Gamma(x) > \Gamma(y) \) for positive numbers, \( x > y > 0 \). Then, \( \Gamma(n + \alpha) \) is evaluated as

\[ \Gamma(n + \alpha) = (n + \alpha - 1)\Gamma(n + \alpha - 1) > (n + \alpha - 1)\Gamma(n - \alpha) \]

where \( n > \alpha \).

Therefore,

\[ |\Gamma(\alpha + n + 2)\Gamma(\alpha - n + 1)| > \left| \frac{\sin \pi(n - \alpha)}{\pi} (\alpha + n + 1)(\alpha + n)(\alpha + n - 1) \right|. \] (12)

Thus,

\[ |a_n| = \left| \frac{(2n + 1)\Gamma(\alpha + 1)\Gamma(n + \alpha + 1)}{(2n + 1)(\alpha + n + 2)\Gamma(\alpha - n + 1)} \right| < M \frac{(2n + 1)}{(\alpha + n + 1)(\alpha + n)(\alpha + n - 1)}. \] (13)

where \( M = \left| \frac{\sin \pi(n - \alpha)}{\pi} \right| \) is a positive number. Hence, \( |a_n| \) decreases faster than or equally to \( n^{-2} \).

### 2.3 Another Representation of Coefficients for Odd-Order Surfaces and a More Strict Theoretical Estimation of Their Decreasing Speed

We present a more detailed formulation for the odd-order case \( (r^{2j+1} = r^{2m}) \). As far as we know, this concrete estimation has not been studied. If \( n \geq k \), substituting the equalities of the gamma function of half-integer

\[ \Gamma \left( \frac{1}{2} + m \right) = \frac{(2m)!}{4^m m! \sqrt{\pi},} \Gamma \left( \frac{1}{2} - m \right) = (4)^m \frac{m!}{(2m)!} \sqrt{\pi} \] (15)

into Eq. (9), we obtain

\[ a_n = 4^{n+k+1} \frac{(n + k + 1)! \{2(n - k)\}!}{(2n)! (2(n - k) - 1)!} \frac{(-1)^{n-k} 2^{k+1}}{(n + k + 1) \cdots (n - k + 1)} \]

\[ \times \frac{4^k k!}{(2n + 4k + 2) \cdots (2n - 2k + 1)} \times (2n + 1)! \left( \frac{2k!}{4^k k!} \right)^2. \] (16)

Since Eq. (15) includes \( 2k + 1 \) terms of \( n \) in the numerator

Thus, the coefficient \( a_n \) decreases as fast as \( n^{-2} \), which is faster than the estimation described in Eq. (14).

For the third-order surface, substituting \( k = 2 \) into Eq. (16), we obtain an explicit expression as

\[ a_n = (-1)^n (2n + 1) \frac{9}{16} \times \frac{2^{10}(n + 3)(n + 2)(n + 1)n(n - 1)}{(2n + 6)(2n + 5)(2n + 4)(2n + 3)(2n + 2)(2n + 1)2n(2n - 1)(2n - 2)(2n - 3)}. \] (17)

Thus, the coefficient \( a_n \) decreases as fast as \( n^{-4} \).

Furthermore for the first-order surface, which describes the cone, substituting \( k = 1 \) into Eq. (16), we obtain an explicit expression as

\[ a_n = (-1)^{n-1} (2n + 1) \]

\[ \times \frac{(n + 2)(n + 1)n(n - 1)}{(2n + 4)(2n + 3)(2n + 2)(2n + 1)2n(2n - 1)} \]

This decreases as fast as \( n^{-2} \), which corresponds to the minimum of decrease described in Eq. (14).

### 2.4 Derivatives of Zernike Polynomials

Derivatives of Zernike polynomials have been already thoroughly discussed. In this paper, we present a simple formulation for the rotationally symmetrical case.

According to Appendix A, it is enough to discuss the derivatives by \( t = r^2 \) instead of the radial coordinate \( r \).
\[ c_m = (2m + 1)\{-(-1)^{n+m} - 1\}. \]  

Therefore, Eq. (19) is represented as
\[ Q_{2k+1}'(t) = 2 \sum_{j=0}^{k} (4j + 1)Q_{2j}(t), \]
\[ Q_{2k}'(t) = 2 \sum_{j=1}^{k} (4j - 1)Q_{2j-1}(t). \]  

For example, the first six terms of this derivation are definitely shown as
\[ Q_0' = 0, \]
\[ Q_1' = 2Q_0, \]
\[ Q_2' = 6Q_1, \]
\[ Q_3' = 2Q_0 + 10Q_2, \]
\[ Q_4' = 6Q_1 + 14Q_3, \]
\[ Q_5' = 2Q_0 + 10Q_2 + 18Q_4. \]  

2.5 Sums of Expansion Coefficients
When we consider \( f(t) = r^t \), then \( f(0) = 0 \) and \( f(1) = 1 \). Since \( Q_n(0) = (-1)^n \) and \( Q_n(1) = 1 \), when substituting \( t = 0, 1 \) into Eq. (4), the following relations hold:
\[ f(0) = a_0 - a_1 + a_2 - \cdots = \sum_{n=1}^{\infty} (-1)^n a_n = 0, \]
\[ f(1) = a_0 + a_1 + a_2 + \cdots = \sum_{n=0}^{\infty} a_n = 1. \]  

By adding and subtracting the two equations of Eq. (24)
\[ \sum_{k=1}^{\infty} a_{2k} = \sum_{k=1}^{\infty} a_{2k-1} = \frac{1}{2}. \]  

3 Uniform Convergence of Zernike Expansion in Shape and Slope for Odd-Order Aspherical Surface
In general, let us consider a function \( g(t) \) and its expansion
\[ g(t) = \sum h_n W_n(t), \]
where \( \{W_n(t)\} \) is an arbitrary sequence of functions. Even though \( g(t) = \sum h_n W_n(t) \) converges uniformly, its termwise differential \( \sum h_n W_n'(t) \) does not necessarily converge to \( g'(t) \).

As shown in Sec. 3, when \( f(t) \) represents an odd-order surface shape, its Zernike expansion \( f(t) = \sum a_n Q_n(t) \) contains an infinite number of terms. In optical ray tracing, since the direction of the exit ray is determined by the surface slope, it is expected that \( \sum a_n Q_n'(t) \) converges to the surface slope \( f'(t) \). In this section, we prove the convergence of both \( f(t) = \sum a_n Q_n(t) \) and \( f'(t) = \sum a_n Q_n'(t) \).

3.1 Convergence of Surface Shapes
We present a proof of the uniform convergence of Eq. (4). For an odd-order surface, \( |a_n| \) decreases faster than or equally to \( r^{-2} \). Since \( |Q_n(t)| \leq 1 \), there exists a positive number \( C \) and an integer \( N \) such that
\[ |a_0Q_0(t) + a_1Q_1(t) + a_2Q_2(t) + \cdots| \leq \sum_{n=0}^{\infty} |a_n| + C \sum_{n=N+1}^{\infty} \frac{1}{n^2} \leq \sum_{n=0}^{\infty} |a_n| + \frac{C\pi^2}{6}. \]  

Thus, we conclude that the convergence of the expansion Eq. (4) for any odd-order surface is uniform and absolute by the Weierstrass M-test.

3.2 Convergence of Surface Slopes
To discuss the convergence of the surface slope of an odd-order surface, let us consider the monomial \( f(t) = r^{2k-1} \) on the interval \([0, 1]\). To guarantee the continuity of the derivative, we suppose that the parameter \( k \geq 2 \) (higher than the third-order surface). Since the case \( k = 1 \) corresponds to the first-order surface or the cone, the original function \( f(t) = \sqrt{t} \) has a singular point at the origin. Although this case is considered as an exceptional case in this paper, similar discussion will be applied to excluding the origin in Sec. 4.

Since the derivative \( f'(t) \) is also continuous, this function is also expanded as
\[ f'(t) = b_0Q_0'(t) + b_1Q_1'(t) + b_2Q_2(t) + \cdots = \sum_{k=0}^{\infty} b_kQ_k(t). \]

By the analogy of Fourier analysis of derivatives, the convergence in slopes is proven if the following two conditions are satisfied:
Condition 1. Convergence of slope: \( \sum_{k=0}^{\infty} b_kQ_k(t) \) converges to \( f'(t) \).
Condition 2. Consistency of termwise differential: the equality
\[ \sum_{k=0}^{\infty} a_nQ_n'(t) = \sum_{k=0}^{\infty} b_kQ_k(t) \]  

holds.

Since \( f'(t) \) is also the odd-order surface of order \((2k-3)/2\), the proof of condition 1 is the direct conclusion of the discussion of Sec. 3.

To show condition 2, we give a straightforward calculation of the left side of Eq. (26). According to the Zernike derivatives formulae Eq. (23), by differentiating Eq. (4) formally
\[ (a_0Q_0(t) + a_1Q_1(t) + a_2Q_2(t) + \cdots)' = 2(a_1 + a_3 + a_5 + \cdots)Q_0 \]
\[ + 6(a_2 + a_4 + a_6 + \cdots)Q_1 \]
\[ + 10(a_3 + a_5 + a_7 + \cdots)Q_2 \]
\[ + 14(a_4 + a_6 + a_8 + \cdots)Q_3 \]
\[ + 18(a_5 + a_7 + a_9 + \cdots)Q_4 \]
\[ + \cdots \]  

(29)
By the procedure described in Appendix B and Eq. (25), the coefficients $b_k$ are

$$
\begin{align*}
    b_0 &= 1 = 2(a_1 + a_3 + a_5 + \cdots), \\
    b_1 &= 6 \left( \frac{1}{2} - a_0 \right) = 6(a_2 + a_4 + a_6 + \cdots), \\
    b_2 &= 10 \left( \frac{1}{2} - a_1 \right) = 10(a_3 + a_5 + a_7 + \cdots), \\
    b_3 &= 14 \left( \frac{1}{2} - a_0 - a_2 \right) = 14(a_4 + a_6 + a_8 + \cdots), \\
    b_4 &= 18 \left( \frac{1}{2} - a_1 - a_3 \right) = 18(a_5 + a_7 + a_9 + \cdots), \\
    b_5 &= 22 \left( \frac{1}{2} - a_0 - a_2 - a_4 \right) = 22(a_6 + a_8 + a_{10} + \cdots).
\end{align*}
$$

Thus, the right side of Eq. (28) is identical to the left side of this equation.

### 3.3 Numerical Confirmation for $f(t) = t^{3/2} = r^3$

By Eq. (17), we obtain

$$
\begin{align*}
    \frac{d}{dt} (t^{3/2}) &= \frac{3}{2} \frac{d}{dt} \left( \frac{Q_0(t)}{2} \right) + \frac{6}{21} \frac{d}{dt} \left( \frac{Q_1(t)}{2} \right) - \frac{2}{165} \frac{d}{dt} \left( \frac{Q_2(t)}{2} \right) \\
    &+ \frac{18}{5005} \frac{d}{dt} \left( \frac{Q_3(t)}{2} \right) - \frac{2}{1365} \frac{d}{dt} \left( \frac{Q_4(t)}{2} \right) \\
    &= \frac{4}{2145} + \frac{28}{143} + \frac{224}{143^2} - \frac{224}{143} \frac{1}{3} + \frac{168}{143} \frac{1}{6} - \frac{24}{65} \frac{1}{6}.
\end{align*}
$$

Also by Eq. (17), the coefficients of derivatives are calculated as follows:

$$
\begin{align*}
    b_0 &= 1, \\
    b_1 &= 6 \left( \frac{1}{2} - a_0 \right) = \frac{3}{5}, \\
    b_2 &= 10 \left( \frac{1}{2} - a_1 \right) = \frac{1}{7}, \\
    b_3 &= 14 \left( \frac{1}{2} - a_0 - a_2 \right) = \frac{1}{15}, \\
    b_4 &= 18 \left( \frac{1}{2} - a_1 - a_3 \right) = \frac{3}{77}.
\end{align*}
$$

Thus, the expansion of the derivatives is

$$
\begin{align*}
    \frac{d}{dt} (t^{3/2}) &= \frac{3}{2} Q_0(t) + \frac{3}{7} Q_1(t) - \frac{1}{15} Q_2(t) + \frac{1}{15} Q_3(t) \\
    &- \frac{3}{77} Q_4(t).
\end{align*}
$$

The fitting errors of Eqs. (31) and (32) are shown in Fig. 1.

To estimate the maximum error versus the number of Zernike polynomials, we present the list of coefficients up to $n = 15$ in Table 1. Since the maximum errors occur at the origin, the errors can be estimated by $\sum_{n=0}^{\infty} (-1)^n a_n$ for the shape and $\sum_{n=0}^{\infty} (-1)^n b_n$ for the slope. Both of them converge to zero when $n \to \infty$.

Since $f(t) = t^{3/2}$ and $f'(t) = (3/2)t^{1/2}$, the decreasing speed of the coefficients is as fast as $n^{-4}$ in shapes by Eq. (17) and $n^{-2}$ in slopes by Eq. (18), respectively. Thus, Zernike expansions both in shape and in slope converge to the original functions. The behaviors of the maximum errors as functions of the number of Zernike terms are shown in Fig. 2.

### 3.4 Approximation for the Cone $f(t) = t^{1/2} = r$

The cone is not an example of smooth odd-order functions. However, as discussed in Secs. 2.3 and 3.1, the Zernike expansion of the cone converges uniformly to $f(t) = t^{1/2}$. Thus, the cone is approximated enough by the Zernike expansion including the origin. Moreover, the similar discussions in Secs. 2.3 and 3.1 can be applied to the cone except at the singular point or the origin. However, the Zernike expansion of $f'(t)$ diverges at the origin because its expansion gives a diverging series.

Actually, by Eq. (19), the expansion coefficients of $f'(t)$ are

$$
\begin{align*}
    b_n &= \frac{1/2(2n + 1)\Gamma(1/2)^2}{\Gamma(3/2 + n)} \frac{1/2}{1/2}.
\end{align*}
$$

By Eq. (19), the denominator is

$$
\begin{align*}
    \Gamma \left( \frac{3}{2} + n \right) \Gamma \left( \frac{1}{2} - n \right) &= \frac{(2n + 2)!}{4^{n+1} (n + 1)!} \sqrt{\pi} \left( -4 \right)^n \frac{1}{(2n)!} \sqrt{\pi} \\
    &= (-1)^n \frac{2n + 1}{4(n + 1)} \pi. \\
\end{align*}
$$

Since $\Gamma(1/2) = \sqrt{\pi}$,
Hence, the sum of the errors for \( b_nQ_n \) is described as

\[
\sum_{k=0}^{n} b_n Q_n(t) = \sum_{k=0}^{n} \frac{2}{\pi} \frac{(-1)^n}{k+1} \frac{1}{k+1} = \sum_{k=0}^{n} \frac{1}{k+1} = \infty. \tag{37}
\]

This conclusion intuitively meets the fact that the cone has a singular point at the vertex.

\( b_n = (-1)^n \). 

Thus,

\[
\sum_{k=0}^{\infty} b_n Q_n(0) = \sum_{k=0}^{\infty} (-1)^n (-1)^n = \sum_{k=0}^{\infty} 1 = \infty. \tag{37}
\]

Hence, the sum \( \sum_{k=0}^{\infty} b_n Q_n(t) \) does not converge at the origin.

Another explanation is possible as follows. Since the cone is described as \( f(t) = t^{1/2} = |r| \) on the interval \([-1, 1]\), the differential is

\[
\frac{df}{dr} = \begin{cases} 
-1 & (r < 0) \\ 
1 & (r > 0) 
\end{cases} . \tag{38}
\]

This conclusion intuitively meets the fact that the cone has a singular point at the vertex.

### 4 Design Example

#### 4.1 Schmidt Surface

In this section, we evaluate the approximation accuracy of the Zernike expansion and discuss the aberration properties of odd-order surfaces via the optical design of the Schmidt corrector plate. The corrector plate is incorporated into the

![Fig. 2](image1.png) Fig. 2 Convergence of the maximum errors for \( f(t) = t^{1/2} \).

![Fig. 3](image2.png) Fig. 3 Layout of Schmidt camera.
Schmidt camera and corrects the spherical aberration of the primary mirror. The optical layout of the Schmidt camera is shown in Fig. 3. Even though corrector surfaces are conventionally designed only with even-order terms containing the power, the design with odd-order terms has been known almost identical. Thus, the third-order surface is almost completely approximated by a finite sum of even-order terms. In addition, since there is the paraxial relation formally. Consequently, we can conclude that this property is one reason for the effectiveness of odd-order surfaces. Even though we have proven that the third-order aspherical surface is fairly approximated by a finite sum of even-order terms.

### 4.2 Design Results and Discussion

We compare the original third-order design with its approximation design by the even-order expansion. To obtain a diffraction-limited design, the third and even orders up to the 16th are needed. By decomposing the third coefficients by Eq. (17) and adding to the original even-order coefficients, we obtain the diffraction-limited design by expanded shape as well, in which even orders up to the 20th are needed. The aspherical coefficients are shown in Table 4.

</tbody>
</table>

The error in shape is shown in Fig. 4. If we use more Zernike terms, the dominant error at the origin will be gradually reduced.

The peak-to-valley error in Fig. 3 is 3.88 \(\times\) 10^{-5} mm, which corresponds to 0.034λ. The comparison of wavefront map and the RMS wavefront ΔW of the two designs is shown in Fig. 3. Note that the RMS wavefront is calculated without considering the central obscuration.

The expanded shape is a fair approximation of the original surface shape. From the viewpoint of practical optical design, the wavefront aberrations in both designs are almost identical. Thus, the third-order surface is almost completely approximated by a finite sum of even-order terms. In addition, since there is the \(A_2\) term in the expanded shape, the third-order surface acts as an aspherical surface containing the power, which is necessary in conventional designs. Although the power term induces slight change in the paraxial relation, the third-order surface does not affect the paraxial relation formally. Consequently, we can conclude that this property is one reason for the effectiveness of odd-order surfaces. Even though we have proven that the third-order aspherical surface is fairly approximated by a finite sum of even-order terms.

Fig. 4 Fitting error in shape.
finite sum of even-order terms, we infer that there are some other reasons for the effectiveness. This is our future issue.

5 Conclusion

In this paper, we have shown that odd-order surfaces are fairly approximated by a finite number of Zernike polynomials. Rearranging the order of monomials, odd-order surfaces are fully approximated by a finite number of even-order power series.

To show this, we have proven the uniform convergence of Zernike expansion of odd-order surfaces both in surface shapes and slopes. By estimating the decreasing speed of the expansion coefficients, any odd-order surface is precisely approximated to be an optical surface by a finite number of Zernike polynomials. In other words, odd-order surfaces are fairly approximated by ordinary even-order aspherical surfaces. For the first-order surface, the Zernike expansion approximates the shape. However, the expansion of the slope does not make sense because the coefficients give a diverging series.

We have demonstrated the result by a design of a Schmidt surface and confirmed that the effect of the third-order surface can be fully expressed by the 20th even-order surface. The power term is necessary in classical design of Schmidt cameras. However, in the calculation of paraxial quantity, odd-order surfaces do not affect values such as focal lengths, paraxial magnifications, and so on. This is one reason why odd-order surfaces are effective in optical design. Since we infer that there are some other reasons for the odd order's effectiveness, this will be our future problem.

Our analysis method is useful for not only analysis of aberration characteristics of aspherical surfaces but also optical measurement especially in the accuracy estimation of approximation of generic surfaces by finite number of terms. Analyzing another expression of odd-order surfaces such as Qcon polynomials is a future issue.

Appendix A: Conversion of the Radial Coordinate in the Derivative Formulae

In the definition of Zernike polynomials Eq. [1] and expansion Eq. [3], the converted coordinate $t = r^2$ is used instead of the original coordinate $r$. Considering that the surface is given by $z = F(x, y)$, due to the law of refraction, the direction of the exit ray is determined by the surface slopes $\partial F/\partial x$ and $\partial F/\partial y$. If $F(x, y)$ is rotationally symmetric, $F(x, y)$ should be a function of $t = r^2$, i.e., $F(x, y) = f(t)$.

Consider the Zernike expansion of $f(t) = \sum a_n Q_n(t)$, the slopes are rewritten as

$$\frac{\partial F}{\partial x} = \frac{\partial t}{\partial x} \frac{df}{dt} = 2x \left( \sum a_n Q_n(t) \right)'$$
$$\frac{\partial F}{\partial y} = \frac{\partial t}{\partial y} \frac{df}{dt} = 2y \left( \sum a_n Q_n(t) \right)'$$

(40)

Thus, in the context of Zernike expansion and its derivatives, it is enough to prove the equality of the termwise derivative $(\sum a_n Q_n(t))' = \sum a_n Q_n'(t)$ and its convergence.

Appendix B: Derivation of the Coefficients $b_k$

We present a straightforward derivation of the expansion coefficients $b_k$. By differentiating Eq. [3] formally, we obtain

$$\langle a_0 Q_0(t) + a_1 Q_1(t) + a_2 Q_2(t) + \cdots \rangle' = 2 \sum_{n=0}^{\infty} \{2 \times 2n + 1\} Q_{2n}(t) \sum_{k=n+1}^{\infty} a_{2k-1}$$
$$+ \{2(2n + 1) + 1\} Q_{2n+1}(t) \sum_{k=n+1}^{\infty} a_{2k}$$

(41)

At this stage, the convergence of Eq. [41] is not guaranteed.

---

**Fig. 5** Design comparison.
The coefficients $b_m$ in Eq. (27) are calculated by the orthogonality of $Q_m(t)$,

$$b_m = (2m + 1) \int_0^1 f'(t)Q_m(t)dt$$

$$= (2m + 1) \left[ f(t)Q_m(t) \right]_0^1 - \int_0^1 f(t)Q_m'(t)dt$$

$$= (2m + 1) \left[ 1 - \int_0^1 f(t)Q_m'(t)dt \right].$$

(42)

This calculation differs according to the parity of $m$. If $m$ is even,

$$b_{2n} = (4n + 1) \left[ 1 - 2 \int_0^1 f(t)Q_{2n}'(t)dt \right]$$

$$= (4n + 1) \left[ 1 - 2 \int_0^1 f(t) \sum_{k=1}^{n} (4k - 1)Q_{2k-1}(t)dt \right].$$

(43)

Since

$$\int_0^1 f(t)(4k - 1)Q_{2k-1}(t)dt = 0$$

$$= \left\{ 2(2k - 1) + 1 \right\} \int_0^1 f(t)Q_{2k-1}(t)dt = a_{2k-1},$$

the expansion coefficient $b_{2n}$ is rewritten as

$$b_{2n} = (4n + 1) \left[ 1 - 2 \sum_{k=1}^{n} a_{2k-1} \right].$$

(44)

By Eq. (45),

$$b_{2n} = 2(4n + 1) \sum_{k=n+1}^{\infty} a_{2k-1}.$$ 

(45)

This is identical to the coefficient of $Q_{2n}(t)$ in Eq. (41) By the same procedure, the case of $m$ is odd is proven, namely,

$$b_{2n+1} = 2(4n + 3) \sum_{k=n+1}^{\infty} a_{2k}.$$ 

(46)

Acknowledgments

The authors would like to thank Mr. Makoto Fujino and Dr. Akira Takada for their valuable suggestions. Also, the authors would like to thank Mr. Shota Obigane, Mr. Yusuke Araki, Mr. Takashi Toriyabe, and Mr. Takayuki Nomura for their useful optical designs.
