Abstract. Transparent optical networks (TON) are becoming increasingly attractive, but transparency introduces security threats, e.g., intrachannel crosstalk attack, to optical networks. In this letter, three attack scenarios, i.e., attack propagation within an optical cross connect (OXC), the secondary attacker traversing successive OXCs and original attacker traversing successive OXCs, are investigated. The scenarios accompanied with gain competition attack are also simulated as comparison. Bit-error-rate (BER) and eye diagram penalties imposed by attack signals with different switch crosstalk intensities and detection methods are presented. The penalties accompanied with gain competition attack are also given. The simulation proved that the original attacker will cause the propagation effect of intrachannel crosstalk attack within three successive OXCs but with limited two stages of optical switches in each OXC. The results also proved that the polluted signals (i.e., the polluted secondary attacker) do not have enough attack capabilities to propagate intrachannel crosstalk attack to the next OXC. The simulation also indicates that if gain competition attack exists, the BER will be somewhat higher.

2 Simulation Analysis and Setup

Figure 2 depicts the simulated TON system, in which four wavelengths are multiplexed in a fiber and all four laser transmitters (TxExtModLaser) transmit at a power of 1 mW. All the transmitted signals are nonreturn to zero (NRZ) formats at a rate of 10 Gbit/s and modulated on four wavelength channels $\lambda_0$, $\lambda_1$, $\lambda_2$, and $\lambda_3$ according to ITU 100 GHz grid from 193.00 to 193.30 THz at C-band. The grid spacing is wide enough to suppress four-wave mixing and cross-phase modulation (XPM) to focus on intrachannel crosstalk attack. However, the extremely high-powered signal will cause serious self-phase modulation (SPM), which causes the broadening of the signal spectrum and power degradation of the attack signal. The statistics of phase difference between legitimate and crosstalk signal which dominates the BER performance is also difficult to determine due to serious SPM, thus multisimulations are carried out by adjusting phase shift in optical switch and we select the worst BER. All segment fibers are nonlinear dispersive fibers.
(NLS) with 0.2 dB/km attenuation and $2.6 \times 10^{-20} \text{m}^2/\text{W}$ nonlinear index. The dispersion for all NLS segments is set identical $2.0 \times 10^{-3} \text{ps/\text{nm/km}}$ also without compensation so that we can concentrate on the crosstalk attack. We employ erbium doped fiber amplifier (EDFA) (AmpSysOpt) as an amplifier with 16 dB fix gain to avoid gain competition attack and 4 dB noise figure. Multiplexer and switch are with 2 dB insertion loss. Node spacings are set to 400 km including five loops of 80 km NLS segments.

We assume that the attacker injects a high-powered signal modulated at the same 10 Gbit/s NRZ format as legitimate signals on wavelength $\lambda_1$ at a power of 500 mW and the injection point is 15 km before OXC-1. In each OXC, three cascaded 2×2 optical switches (SwitchDos-Y-Two) are set for channel $\lambda_1$. Let $\lambda_{1,n}$ represent the legitimate signal on wavelength $\lambda_1$ passing the $n$'th stage of an optical switch. The high-powered attacker on wavelength $\lambda_1$ will attack legitimate signals $\lambda_{1,1}, \lambda_{1,2}$ and $\lambda_{1,3}$ from OXC-1 to OXC-6, as shown in Fig. 2. The polluted signal in OXC-1 directly traverses OXC-7 and OXC-8. At the egress points of each switches (i.e., the point labeled as @), BERs and eye diagrams are detected using RxBERs and ViScopes.

3 Simulation and Discussion

3.1 Intrachannel Crosstalk Attack Propagation Within OXC

We assume the crosstalk to be Gaussian distribution to achieve the upper bound of system BER (Ref. [10] and the statistics of the received optical signal will follow one of a family of Chi-squared probability densities [11, 12] and then the Chi-squared method is set to estimate the BER at the receivers. As a comparison, the Gaussian method is also implemented, in which the statistics of the received optical signal are assumed to be Gaussian distribution. Switch crosstalk intensity is a parameter representing the amount of power leakage between two channels in an optical switch, which determines how much crosstalk noise will be added in the received optical signals. Figure 3 illustrates the BER of signals $\lambda_{1,1}, \lambda_{1,2}, \lambda_{1,3}$ in OXC-1. As switch crosstalk intensity decreases from $-20$ to $-35$ dB in four grades, i.e., $-20, -25, -30, -35$ dB, the BERs for $\lambda_{1,1}$ are affected between 0.1 and 0.5, and those for $\lambda_{1,2}$ are distinguished. However, BERs for $\lambda_{1,3}$ are all kept lower. Eye diagrams for $\lambda_{1,2}$ with different switch crosstalk intensities under Chi-squared detection are also given in Fig. 3. The result reveals that the extent of intrachannel attack propagation within an OXC is different with switch crosstalk intensities but with limited two stages of switches. The result also indicates that as the crosstalk increases, there will be less difference between detection methods. Compared to the Gaussian method, the Chi-squared method will overestimate the system BER.
3.2 Original Attacker Traversing Successive OXCs

To investigate the intrachannel crosstalk attack spanning multiple OXCs, the original attack signal is set to traverse from OXC-1 to OXC-6. The switch crosstalk intensity is set to be identically $-25$ dB at all switches. Figure 5(a) shows the BERs of $\lambda_{1,1}$, $\lambda_{1,2}$, and $\lambda_{1,3}$ in OXC-2 to OXC-6, respectively. The BERs of $\lambda_{1,1}$ at OXC-2 and OXC-3 are 0.3 and $1.05 \times 10^{-5}$, respectively. The BER of $\lambda_{1,1}$ at OXC-4, -5, and -6 are all quickly dropped. Those BERs of $\lambda_{1,2}$ and $\lambda_{1,3}$ at five OXCs are all less than $1.0 \times 10^{-10}$. Eye diagrams of $\lambda_{1,1}$ in OXC-2 to OXC-5 are shown in Fig. 6. By setting EDFA to power model, a gain competition effect can be achieved. Figure 5(b) shows the BER penalties accompanied with gain competition attack. The results also indicate that only the first stage of switches will be affected worse if gain competition attack exists. The simulations indicate that the high-powered signal will propagate an intrachannel crosstalk attack to successive three OXCs but with limited two stage switches within each OXC, and this propagation extent depends on switch crosstalk intensity and detection method. The secondary attacker does not have enough attack capability to propagate this attack. We also found if gain competition exists, the system BER will be somewhat higher.

3.3 Secondary Attacker Traversing Successive OXCs

The intrachannel crosstalk propagation caused by the polluted signal (secondary attacker) is also simulated. As illustrated in Fig. 2, the secondary attacker from OXC-1 traverses OXC-7 and OXC-8 and attacks $\lambda_{1,1}$, $\lambda_{1,2}$, and $\lambda_{1,3}$ in the OXCs with BERs all being below $1.0 \times 10^{-9}$ as shown in Fig. 5(a). If gain competition attack exists, as shown in Fig. 5(b), the BER of $\lambda_{1,1}$ in OXC-7 and OXC-8 are getting a little higher. The simulations indicate that the polluted secondary attacker does not have enough capabilities to propagate intrachannel attack to successive OXCs even if gain competition attack exists, for the reason that insertion loss in optical components and nonlinear effect in fibers cause power degradation of the secondary attacker.

4 Conclusions

In this letter, three attack scenarios of intrachannel crosstalk accompanied with gain competition attack have been presented and investigated via VPItransMaker™. We found that the high-powered signal will propagate an intrachannel crosstalk attack to successive three OXCs but with limited two stage switches within each OXC, and this propagation extent depends on switch crosstalk intensity and detection method. The secondary attacker does not have enough attack capability to propagate this attack. We also found if gain competition exists, the system BER will be somewhat higher.
