Properties of the Mean Acquisition Time for Wide-Bandwidth Signals in Dense Multipath Channels

Watcharapan Suwansantisuk, Moe Z. Win, and Lawrence A. Shepp

ABSTRACT

This paper investigates important properties of acquisition receivers that employ commonly used serial-search strategies. In particular, we focus on the properties of the mean acquisition time (MAT) for wide bandwidth signals in dense multipath channels. We show that a lower bound on the MAT over all possible search strategies is the solution to an integer programming problem with a convex objective function. We also give an upper bound expression for the MAT over all possible search strategies. We demonstrate that the MAT of the fixed-step serial search (FSSS) does not depend on the location of the first resolvable path within the uncertainty region, thereby simplifying the evaluation of the MAT of the FSSS. The results in this paper can be applied to the design and analysis of fast acquisition systems in various wideband scenarios.

Keywords: Acquisition, non-consecutive serial search, spread-spectrum, dense multipath channels

1. INTRODUCTION

Wide bandwidth transmission systems have emerged as a ubiquitous wireless technology due to their advantages over traditional narrowband systems and have received considerable attention from the military, commercial, and scientific sectors [1–3]. Wide bandwidth transmission systems provide low probability of detection and interception, and allow secure communication in wireless networks. They operate well in extremely challenging environments, such as dense urban, confined, and dense multipath areas, in which ordinary communication systems may fail to provide reliable transmission. Due primarily to their fine delay resolution properties, wide bandwidth signals are robust against fading and are able to provide accurate positioning.

One of the most common forms of wide bandwidth signaling is to employ spread-spectrum techniques. A spread-spectrum receiver must perform a sequence synchronization, which is required before commencing any communication between the end points. The synchronization process occurs in two stages: the acquisition stage and the tracking stage [4–7]. Synchronization time greatly depends on how the receiver performs the acquisition stage, and the acquisition requirement may even limit the capacity of a wireless network [8]. Thus, this paper focuses on the issues related to acquisition.

During the acquisition stage, a receiver performs several tasks. It coarsely aligns the locally generated reference (LGR) sequence with the received signal sequence by testing whether the LGR phase is within the required accuracy of the received signal sequence phase. If not, the receiver will set the new LGR phase according to some prescribed strategy. If the LGR phase is within the required accuracy, the receiver will enter the tracking stage, finely align the two sequences, and maintain the synchronization throughout the communication. In general, the goal of the acquisition system is to minimize the mean acquisition time (MAT), the average duration to complete the acquisition stage.

L. A. Shepp is with the Department of Statistics, Rutgers University, Piscataway, NJ 08854 USA (e-mail: shepp@stat.rutgers.edu).
Important parameters associated with the acquisition stage are the total number \( N_{\text{unc}} \) of phases (cells) to be tested and the number \( N_{\text{hit}} \) of correct phases (in-phase cells). The expression for \( N_{\text{unc}} \) is given by

\[
N_{\text{unc}} = T_{\text{unc}} / T_{\text{res}},
\]

where \( T_{\text{unc}} \) is the range of the phase delay’s uncertainty and \( T_{\text{res}} \) is the accuracy with which the receiver needs to resolve the phase delay. Without loss of generality, cells are indexed from 1 to \( N_{\text{unc}} \), and the uncertainty index set

\[
U \triangleq \{1, 2, 3, \ldots, N_{\text{unc}}\}
\]
denotes a collection of cells to test. Among these \( N_{\text{unc}} \) cells, \( N_{\text{hit}} \) cells correspond to the in-phase cells. The set \( \mathcal{H}_{\text{hit}} \subset U \) of in-phase cells depends on the phase delays of the resolvable paths, associated with the operating environment.

The set of in-phase cells for a dense multipath channel can be characterized as follows. In such a channel, propagation paths tend to arrive in a cluster [9–12]. As a result, if a random variable \( B \in U \) denotes the cell that corresponds to the delay of the first propagation path, the set of in-phase cells conditioned on \( B = b \) is given by

\[
\mathcal{H}_{\text{hit}}(b) \triangleq \{b, b \oplus 1, \ldots, b \oplus (N_{\text{hit}} - 1)\}.
\]

Here, the symbol \( \oplus \) denotes the modulo \( N_{\text{unc}} \) addition defined by \( x \oplus y \triangleq x + y - lN_{\text{unc}} \) for some unique integer \( l \) such that \( x + y - lN_{\text{unc}} \in U \).

For wide bandwidth transmission systems, achieving acquisition in a reasonable amount of time can be a very challenging task. In particular, the number \( N_{\text{unc}} \) of cells that the receiver needs to test can be very large for a wide bandwidth transmission system, since the quantity \( 1/T_{\text{res}} \) in (1) is proportional to the transmission bandwidth. This challenge necessitates an approach to improve the MAT.

One important approach to improve the MAT is to use an intelligent order to test cells. A search order can be described by a permutation function \( \pi \) of a set \( U \). The set of all possible search orders is given by

\[
P = \{\pi \mid \pi: U \to U \text{ is a permutation function and } \pi(1) = 1\},
\]

where the condition \( \pi(1) = 1 \) simply removes some redundant permutations from \( P \).

Search orders that have been used in the literature include the conventional serial search (CSS) [13,14], the fixed-step serial search (FSSS) [15–19], and the bit-reversal search [15–18]. In general, search orders affect the MAT, and the notation \( \mathbb{E}\{T_{\text{ACQ}}(\pi)\} \) denotes the MAT as a function of a search order \( \pi \).

For a given \( \pi \), the MAT can be evaluated by using flow diagrams [18–22], each corresponding to a different possible position \( B = b \) of the first resolvable path. The tuple \( (\pi, b) \in P \times U \) characterizes the structure of the flow diagram, and we refer to this tuple as a description. Note that the flow diagram has one absorption state representing the event of successful acquisition. The average time to arrive at the absorption state is known as the absorption time. This quantity is important and closely related to the MAT.

Although the expression for the MAT, \( \mathbb{E}\{T_{\text{ACQ}}(\pi)\} \), can be evaluated for a given \( \pi \) [18–23], important properties of the MAT cannot be derived easily. For example bounds on the minimum MAT, \( \min_{\pi \in P} \mathbb{E}\{T_{\text{ACQ}}(\pi)\} \), are difficult to obtain from the direct optimization over the set of search orders \( P \). The difficulty arises from the fact that the conventional expression of the MAT does not reveal its dependence on the search order \( \pi \) explicitly. To alleviate this difficulty, we propose to transform the set of descriptions into the set of spacing rules. It will be apparent that this transformation discloses important properties of the absorption time and enables the investigation of the implications of the absorption time’s properties for the MAT.

This paper investigates important properties of the MAT for wide-bandwidth signals in dense multipath environments. Contributions of the paper are as follows:

\[\text{To emphasize the dependence of } \mathcal{H}_{\text{hit}} \text{ on } B = b, \text{ we will explicitly write } \mathcal{H}_{\text{hit}}(b) \text{ as a function of } b.\]

\[\text{The acquisition time is a random variable, and the randomness arises from noise, fading, and, possibly, a randomized decision rule at the detection layer.}\]

\[\text{Our approach follows the general philosophy of solving difficult problems in the transform domains [24].}\]
a transformation of a set of descriptions into a set of spacing rules,
• a proof that the absorption time expression in the transform domain is of a quadratic form with a positive
definite Hessian matrix,
• a proof that the MAT is lower bounded by the solution of an optimization problem, which can be solved
algorithmically using well-known methods in convex optimization,
• an explicit upper bound expression for the MAT, and
• a simplification of the MAT expression when the FSSS is employed.

The results here are valid in a broad class of fading conditions, receivers’ implementations, and operating envi-
ronments.

This paper is organized as follows. Section 2 outlines the system model. Section 3 derives the absorption
time expression in a transform domain. Important properties of the absorption time and important properties
of the MAT are proved in Section 4 and Section 5, respectively. Section 6 concludes the paper and summarizes
important findings.

2. SYSTEM MODEL

We consider a receiver that employs a widely used serial-search strategy [13–23]. The sequence of phases or
cells that the receiver tests during the acquisition stage is given by
\[ \pi(k), \pi(k+1), \ldots, \pi(N_{\text{unc}}), \pi(1), \pi(2), \ldots, \pi(N_{\text{unc}}), \pi(1), \pi(2), \ldots \]  
(5)
where \( \pi(k) \) is the first cell that the receiver examines. The subsequence \( \{\pi(i)\}_{i=1}^{N_{\text{unc}}} \) in (5) is repeated to
illustrate the fact that, due to noise and fading, the receiver may take several rounds to test the cells before it
finds a correct cell.

Search orders that have been used in the literature are shown in Fig. 1. Note from the figure that a search
order controls the arrangement of non-absorbing states in a flow diagram. The CSS [13, 14], where the consecutive
cells are tested serially, corresponds to the search order
\[ \pi^1(i) = i. \]  
(6)
The FSSS [15–19], which skips \( N_J \geq 1 \) cells after each test, corresponds to the search order
\[ \pi^{N_J}(i) = 1 \oplus (i - 1)N_J. \]  
(7)
Note that \( N_J \) and \( N_{\text{unc}} \) are required to be relatively prime, so that \( \pi^{N_J}(\cdot) \) in (7) is a permutation function and,
consequently, a member of \( P \). Clearly, the CSS \( \pi^1 \) is a special case of the FSSS \( \pi^{N_J} \) with the step size \( N_J = 1 \).
The bit-reversal serial search [15–18], where the receiver tests the cells in a random-like order, corresponds to
the search order \( \pi_R \), defined as follows. For \( i \neq j \),
\[ \pi_R(i) < \pi_R(j) \iff \text{rev}(i) < \text{rev}(j), \]  
(8)
where \( \text{rev}(i) \) is the reversal of the \( \lceil \log_2 N_{\text{unc}} \rceil \) binary digit representation of the integer \( i - 1 \). Equation (8)
specifies the unique order of \( N_{\text{unc}} \) cells in the uncertainty index set: assigning the cost \( \text{rev}(i) \) to cell \( i \) and
arranging the cells in ascending order according to their costs.

A flow diagram represents the details of the acquisition stage, such as the set \( \mathcal{H}_{\text{hit}}(\cdot) \) of correct cells, the search
order being employed, and the durations and the probabilities associated with the signal detection procedure.
Fig. 2 depicts a flow diagram with a generic search order \( \pi \). The important details of the flow diagram are as
follows. The flow diagram contains \( N_{\text{unc}} + 1 \) states: one absorbing state, \( \mathcal{H}_{\text{hit}} \) states of type \( H_1 \), and \( N_{\text{unc}} - N_{\text{hit}} \)
states of type \( H_0 \). The absorbing state \( \text{ACQ} \) represents the event of successful acquisition. Each \( H_1 \)-type state
corresponds to an in-phase cell, while each $H_0$-type state corresponds to a non-in-phase cell. Conditioned on $B = b$, the set of $H_1$ states in (3) can be written in terms of $\pi$ as

$$\{\pi(k_1), \pi(k_2), \ldots, \pi(k_{N_{\text{hit}}})\} = H_{\text{hit}}(b)\tag{9}$$

for some unique integers $1 \leq k_1 < k_2 < \cdots < k_{N_{\text{hit}}} \leq N_{\text{unc}}$. In a flow diagram, those $H_1$-states $\pi(k_i)$ have transition paths to the absorbing state.

The probability that the receiver begins a test at any cell is equal to $1/N_{\text{unc}}$. This uniform probability indicates that the receiver has no a priori knowledge of the location of a correct cell. The transition paths’ parameters $P_D$, $P_M \equiv 1 - P_D$, $\tau_D$, $\tau_M$, and $\tau_P$ are effective probabilities and durations associated with the signal detection procedure. For the purpose of MAT calculation, these parameters can be derived from a generic path gain $H_D(z)$ from an $H_1$-state to ACQ, a generic path gain $H_M(z)$ from an $H_1$-state to the adjacent non-absorbing state, and a generic path gain $H_0(z)$ from an $H_0$-state to the adjacent non-absorbing state [16]. In turn, the details of the signal detection procedure determine $H_D(z)$, $H_M(z)$, and $H_0(z)$ [20–22]. With all these features, a flow diagram is a single-absorbing-state Markov chain, having transition probabilities and transition times written in polynomial forms.

Flow diagrams are used to find the absorption times and the MAT. The MAT is a convex combination of the
Figure 2. A generic flow diagram for the serial search with an arbitrary search order $\pi$ contains $N_{\text{unc}} + 1$ states. The state labeled ACQ is the absorbing state. The states in thick circles are $H_1$-states, corresponding to the in-phase cells. The remaining states are $H_0$-states, corresponding to the non-in-phase cells.

Absorption times and is given by

$$
\mathbb{E}\{T_{\text{ACQ}}(\pi)\} = \sum_{b=1}^{N_{\text{unc}}} \mathbb{E}\{T_{\text{ACQ}}(\pi) \mid B = b\} \cdot \Pr\{B = b\} \\
= \sum_{b=1}^{N_{\text{unc}}} f(\pi, b) \cdot \Pr\{B = b\},
$$

where $f(\pi, b)$ denotes the absorption time of the flow diagram with a search order $\pi$ and the set $\mathcal{H}_{\text{hit}}(b)$ of in-phase cells. A conventional approach of finding the absorption time yields the absorption time expression

$$
f(\pi, b) = \frac{1}{N_{\text{unc}}} \frac{d}{dz} \left( \frac{\sum_{k=1}^{N_{\text{unc}}} \sum_{i=1}^{N_{\text{unc}}} H_i^b(z \oplus k)(z) \prod_{j=1}^{i} H_{\pi(j \oplus k)}^b(z)}{1 - \prod_{i=1}^{N_{\text{unc}}} G_i^b(z)} \right) \bigg|_{z=1},
$$

where the polynomials $H_i^b(z)$ and $G_i^b(z)$ depend on the path gains and equal

$$
H_i^b(z) = \begin{cases} 
P_D z^{\tau_D} & i \in \mathcal{H}_{\text{hit}}(b) \\
0 & \text{otherwise,}
\end{cases}
$$

and

$$
G_i^b(z) = \begin{cases} 
P_M z^{\tau_M} & i \in \mathcal{H}_{\text{hit}}(b) \\
z^{\tau_P} & \text{otherwise.}
\end{cases}
$$
Equation (11) follows from a loop-reduction technique, which is used to find the MATs in [18–22].

Although the expressions (10) and (11) are suitable for finding the MAT for a given search order, they are not suitable for deriving some important properties of the MAT. Note that the expression (11) does not reveal how the absorption time depends on $\pi$ explicitly. Thus, it is unclear how one can derive or bound the minimum MAT, $\min_{\pi \in P} \mathbb{E} \{ T_{ACQ}(\pi) \}$, and the maximum MAT, $\max_{\pi \in P} \mathbb{E} \{ T_{ACQ}(\pi) \}$, using the expressions (10) and (11).

To alleviate this difficulty, we transform the set of descriptions into the set of spacing rules, following the general philosophy of solving difficult problems in the transform domains [24]. It will be apparent in the following sections that this transformation provides us with important properties of the MAT.

![Figure 3](https://www.spiedigitallibrary.org/conference-proceedings-of-spie/conference-proceedings-of-spie-restricted/5847/article-126.pdf)

**Figure 3.** The spacing rule $\mathbf{m} = [m_1 \ m_2 \ \ldots \ m_{N_{hit}}]^T$ characterizes the structure of the flow diagram.

A spacing rule is an element of the set

$$\mathcal{S} = \left\{ \left[m_1 \ m_2 \ \ldots \ m_{N_{hit}}\right]^T \left| \sum_{i=1}^{N_{hit}} m_i = N_{unc} - N_{hit}; \forall i, \text{integer } m_i \geq 0 \right. \right\}. \ (12)$$

A flow diagram with a spacing rule $\mathbf{m} \triangleq [m_1 \ m_2 \ \ldots \ m_{N_{hit}}]^T$ has an $H_1$-state, which is followed by $m_1$ $H_0$-states, which are followed by another $H_1$-state, which is followed by $m_2$ $H_0$-states, and so on (see Fig. 3). Clearly, the sum $\sum_{i=1}^{N_{hit}} m_i$ must equal the number $N_{unc} - N_{hit}$ of $H_0$-states. Like a description $(\pi, b)$, a spacing rule characterizes the structure of a flow diagram and strongly affects the absorption time.

A relationship between a description $(\pi, b)$ and the spacing rule exists. In particular, a flow diagram with a search order $\pi$ and the set $\mathcal{H}_{hit}(b)$ of in-phase cells has the spacing rule $[m_1 \ m_2 \ \ldots \ m_{N_{hit}}]^T$, defined as follows:

$$m_i \triangleq \begin{cases} k_{i+1} - k_i - 1 & i = 1, 2, \ldots, N_{hit} - 1 \\ k_1 + N_{unc} - k_{N_{hit}} - 1 & i = N_{hit} \end{cases}$$
for the unique integers $1 \leq k_1 < k_2 < \cdots < k_{N_{\text{hit}}} \leq N_{\text{unc}}$ satisfying (9). A mapping from a description $(\pi, b)$ to the corresponding spacing rule is denoted by $s: \mathcal{P} \times \mathcal{U} \to \mathcal{S}$.

Transforming a description $(\pi, b)$ into a spacing rule provides us with some important properties of the MAT. For example, we will see in Section 5 that if $v(\cdot)$ denotes the absorption time as a function of a spacing rule, the MAT will be lower bounded and upper bounded respectively by the integer programming problems $\min_{m \in S} v(m)$ and $\max_{m \in S} v(m)$. There are well-known techniques to solve such problems [25–27]. In the next section, we derive the explicit expression of $v(\cdot)$.

### 3. ABSORPTION TIME EXPRESSION

The goal of this section is to derive the explicit absorption time expression $v(m)$ as a function of $m \in S$.

**Theorem 3.1 (Absorption Time).** The absorption time of the flow diagram with the spacing rule $m \in S$ is given by

$$v(m) = \frac{1}{2} m^T H m + c,$$

where

$$H_{ij} = \frac{\tau_P}{N_{\text{unc}} (1 - P_M^{N_{\text{hit}}})} \left[ P_M^{N_{\text{hit}} - |i-j|} + P_M^{|i-j|} \right], \quad 1 \leq i, j \leq N_{\text{hit}},$$

$$c = \left( 1 - \frac{N_{\text{hit}}}{N_{\text{unc}}} \right) \cdot \left( \frac{1 + P_M}{1 - P_M} \right) \frac{\tau_P}{2} + \frac{P_M}{1 - P_M} \tau_M + \tau_D,$$

with $0^0 \triangleq 1$.

The details of the proof can be found in [15, 16]. The essential idea of the proof uses the fact that the flow diagram has one absorption state, thereby finding the absorption time reduces to solving a system of linear equations.

Note that when $P_M = 1$, i.e., the acquisition receiver misses the correct cell with probability one, the absorption time is unbounded. Therefore, we will assume that $P_M \in [0, 1)$ in the following sections.

### 4. ABSORPTION TIME PROPERTIES

The goal of this section is to prove properties of the absorption time.

**Theorem 4.1 (Convexity).** The function $v(\cdot)$ is convex on $\mathbb{R}^{N_{\text{hit}}}$.

**Proof.** Since the coefficient $\frac{\tau_P}{N_{\text{unc}} (1 - P_M^{N_{\text{hit}}})}$ in (14) is positive for $P_M \in [0, 1)$, it is sufficient to prove that the $N_{\text{hit}} \times N_{\text{hit}}$ matrix $A$, in which the $i_j^{th}$ entries are given by

$$A_{ij} \triangleq \left[ P_M^{N_{\text{hit}} - |i-j|} + P_M^{|i-j|} \right],$$

is non-negative definite. When $P_M = 0$, the matrix $A$ is an identity matrix since $0^0 \triangleq 1$ (see Thm. 3.1), and thus $A$ is non-negative definite. Therefore, we will consider only $P_M$ in the range $0 < P_M < 1$.

The matrix $A$ can be generated from the kernel

$$K(s, t) = \theta e^{s+|s-t|} + e^{-|s-t|}, \quad -T \leq s, t \leq T,$$

where $T \triangleq -\left( \frac{N_{\text{hit}}}{2} - \frac{1}{4} \right) \ln P_M$ and $\theta \triangleq P_M^{N_{\text{hit}}}$. In particular, the $i_j^{th}$ entries of $A$ are given by $A_{ij} = K(t_i, t_j)$, where

$$t_k \triangleq -\left( \frac{2k - N_{\text{hit}} - 1}{2} \right) \ln P_M, \quad k = 1, 2, 3, \ldots, N_{\text{hit}}.$$
Figure 4. Entries of the matrix $A$ are generated from the non-negative definite kernel $K(s, t)$. We show the case when $A$ is $N_{hit} \times N_{hit} = 6 \times 6$.

Note that $t_k \in (-T, T)$ is in a valid range. See Fig. 4 for an illustration.

Next, we show that $A$ is non-negative definite. Assume to the contrary that there exists $x = [x_1 \ x_2 \ldots \ x_{N_{hit}}]^T \in \mathbb{R}^{N_{hit}}$ such that $x^T A x < 0$. For an integer $n \geq 1$, let

$$p_n(t) = \begin{cases} n^2 t + n & \text{if } t \in \left[ -\frac{1}{n}, 0 \right], \\ -n^2 t + n & \text{if } t \in \left( 0, \frac{1}{n} \right), \\ 0 & \text{otherwise}. \end{cases}$$

Define $x_n(t) = \sum_{i=1}^{N_{hit}} x_i p_n(t - t_i)$ (see Fig. 5 for an illustration) and consider a sequence $\{y_n\}$, where $y_n = \int_{-T}^T \int_{-T}^T x_n(s) K(s, t) x_n(t) ds dt$. Since $\lim_{n \to \infty} y_n = x^T A x$, we can select $m$ large enough so that $y_m < 0$.

Our proof will show the non-negative definiteness of $A$ from the non-negative definiteness of $K(s, t)$. It is interesting to further investigate the positive definiteness of our matrix $A$.
It is easy to verify that $T > 0$ and $-e^{-2T} < \theta < e^{-2T}$. Therefore, by Lemma A.1 in Appendix A, $K(s, t)$ is non-negative definite. Note that $x_m(t) \in \mathcal{L}^2$, and, thus, $y_m \geq 0$. Hence, we have a contradiction. That completes the proof. \[\square\]

The next theorem deals with rotational invariance and reversal invariance. Let the rotation and the reversal of any $x \in \mathbb{R}^{N_{hit}}$ be defined respectively as follows:

$$\text{rot} \left\{ [x_1 \ x_2 \ \ldots \ x_{N_{hit}}]^T \right\} \triangleq [x_2 \ x_3 \ \ldots \ x_1]^T \quad (16)$$

$$\text{rev} \left\{ [x_1 \ x_2 \ \ldots \ x_{N_{hit}}]^T \right\} \triangleq [x_{N_{hit}} \ x_{N_{hit}-1} \ \ldots \ x_1]^T \quad (17)$$

Notice that if $m$ is a spacing rule, then $\text{rot} \{m\}$ and $\text{rev} \{m\}$ are also spacing rules. The next theorem establishes the relationship among the absorption times corresponding to the spacing rules $m$, $\text{rot} \{m\}$, and $\text{rev} \{m\}$.

**Theorem 4.2 (Rotational Invariance, Reversal Invariance).** For every $m \in S$,

$$v(m) = v(\text{rot} \{m\}) = v(\text{rev} \{m\}).$$

**Proof.** For $1 \leq i, j \leq N_{hit}$, let $h_{i,j}$ denote the $ij$th entry of matrix $H$ and $h_i$ denote the $i$th column of $H$. Let any spacing rule $m$ be given.

To prove the rotational invariance property, we note that

$$m^T H m = m^T \begin{bmatrix} h_2 & h_3 & \ldots & h_{N_{hit}} & h_1 \end{bmatrix} \text{rot} \{m\}$$

$$\overset{(a)}{=} \text{rot}^T \{m\} \begin{bmatrix} \text{rot} \{h_2\} & \text{rot} \{h_3\} & \ldots & \text{rot} \{h_{N_{hit}}\} & \text{rot} \{h_1\} \end{bmatrix} \text{rot} \{m\}$$

$$\overset{(b)}{=} \text{rot}^T \{m\} H \text{rot} \{m\}.$$ 

The equality (a) follows from the fact that

$$x^T y = \text{rot}^T \{x\} \text{rot} \{y\}, \quad \text{for any } x, y \in \mathbb{R}^{N_{hit}}.$$ 

The equality (b) follows from the fact that $h_{i,j} = h_{i \oplus 1, j \oplus 1}$ for any $1 \leq i, j \leq N_{hit}$, which implies that $\text{rot} \{h_i\} = h_{i \oplus 1}$ for any $1 \leq i \leq N_{hit}$. Therefore, $v(m) = v(\text{rot} \{m\})$.

To prove the reversal invariance property, we note that

$$m^T H m = m^T \begin{bmatrix} h_{N_{hit}} & h_{N_{hit}-1} & \ldots & h_2 & h_1 \end{bmatrix} \text{rev} \{m\}$$

$$\overset{(a)}{=} \text{rev}^T \{m\} \begin{bmatrix} \text{rev} \{h_{N_{hit}}\} & \text{rev} \{h_{N_{hit}-1}\} & \ldots & \text{rev} \{h_2\} & \text{rev} \{h_1\} \end{bmatrix} \text{rev} \{m\}$$

$$\overset{(b)}{=} \text{rev}^T \{m\} H \text{rev} \{m\}.$$ 

The equality (a) follows from the fact that

$$x^T y = \text{rev}^T \{x\} \text{rev} \{y\}, \quad \text{for any } x, y \in \mathbb{R}^{N_{hit}}.$$ 

The equality (b) follows from the fact that $h_{i,j} = h_{(N_{hit} - i + 1) \oplus (N_{hit} - j + 1)}$ for any $1 \leq i, j \leq N_{hit}$, which implies that $h_i = \text{rev} \{h_{N_{hit} - i + 1}\}$ for any $1 \leq i \leq N_{hit}$. Therefore, $v(m) = v(\text{rev} \{m\})$. That completes the proof. \[\square\]
5. MAT PROPERTIES

In this section, we will use the absorption time’s properties to derive important properties of the MAT.

**Theorem 5.1 (Lower Bound).** The MAT of any search order \( \pi \) satisfies

\[
\min_{m \in S} v(m) \leq \mathbb{E} \{ T_{ACQ}(\pi) \}.
\]

**Proof.** Using the expression for the MAT yields

\[
\mathbb{E} \{ T_{ACQ}(\pi) \} = \sum_{b=1}^{N_{\text{unc}}} f(\pi, b) \cdot \Pr \{ B = b \}
= \sum_{b=1}^{N_{\text{unc}}} v(s(\pi, b)) \cdot \Pr \{ B = b \}
\geq \sum_{b=1}^{N_{\text{unc}}} \min_{(\pi, b) \in \mathcal{P} \times \mathcal{U}} v(\tilde{s}(\pi, b)) \cdot \Pr \{ B = b \}
= \sum_{b=1}^{N_{\text{unc}}} \min_{m \in S} v(m) \cdot \Pr \{ B = b \}
= \min_{m \in S} v(m).
\]

That completes the proof. \( \square \)

Note that the objective function \( v(\cdot) \) is convex on \( \mathbb{R}^{N_{\text{hit}}} \) by Thm. 4.1, and well-known techniques for solving integer programming problems with convex objective functions are available [27].

**Theorem 5.2 (Upper Bound).** The MAT of any search order \( \pi \) satisfies

\[
\mathbb{E} \{ T_{ACQ}(\pi) \} \leq T_{\text{max}},
\]

where

\[
T_{\text{max}} \triangleq v([N_{\text{unc}} - N_{\text{hit}} \ 0 \ 0 \ 0 | 0]^T)
= \left( \frac{N_{\text{unc}} - N_{\text{hit}}}{N_{\text{unc}}} \right)^2 \cdot \left( \frac{1 + P_{M}^{N_{\text{hit}}}}{1 - P_{M}^{N_{\text{hit}}}} \right) \frac{\tau_p}{2} + \left( 1 - \frac{N_{\text{hit}}}{N_{\text{unc}}} \right) \cdot \left( \frac{1 + P_{M}}{1 - P_{M}} \right) \frac{\tau_p}{2} + \frac{P_{M}}{1 - P_{M}} \tau_M + \tau_D.
\]

**Proof.** For \( 1 \leq i \leq N_{\text{hit}} \), let \( \mathbf{e}_i = [0 \ldots 0 \ 1 \ 0 \ldots 0]^T \) denote a standard basis vector in \( \mathbb{R}^{N_{\text{hit}}} \) with one and only one non-zero element at the \( i^{th} \) component. Let \( \mathcal{E} \triangleq \{(N_{\text{unc}} - N_{\text{hit}})\mathbf{e}_i, \text{ for all } 1 \leq i \leq N_{\text{hit}}\} \) denote a subset of \( \mathcal{S} \). Clearly, \( \mathcal{E} \) forms a basis for \( \mathbb{R}^{N_{\text{hit}}} \).

Any spacing rule \( \mathbf{m} = [m_1 \ m_2 \ldots \ m_{N_{\text{hit}}}]^T \in \mathcal{S} \subset \mathbb{R}^{N_{\text{hit}}} \) can be written as

\[
\mathbf{m} = \sum_{i=1}^{N_{\text{hit}}} \lambda_i \cdot [(N_{\text{unc}} - N_{\text{hit}})\mathbf{e}_i],
\]

where

\[
\lambda_i = \frac{m_i}{N_{\text{unc}} - N_{\text{hit}}} \quad i = 1, 2, \ldots, N_{\text{hit}}.
\]

Note that \( \lambda_i \geq 0 \), for \( i = 1, 2, \ldots, N_{\text{hit}} \) and \( \sum_{i=1}^{N_{\text{hit}}} \lambda_i = 1 \). Thus, \( \mathbf{m} \) in (18) is written as a convex combination of the spacing rules in \( \mathcal{E} \).
Recall that \( v(\cdot) \) is convex on \( \mathbb{R}^{N_{\text{hit}}} \) (Thm. 4.1). Then, we have
\[
v(m) \leq \sum_{i=1}^{N_{\text{hit}}} \lambda_i \cdot v((N_{\text{unc}} - N_{\text{hit}}) e_i)
\]
\[
\leq \sum_{i=1}^{N_{\text{hit}}} \lambda_i \cdot v((N_{\text{unc}} - N_{\text{hit}}) e_1)
\]
\[
= v((N_{\text{unc}} - N_{\text{hit}}) e_1)
\]
\[
\leq T_{\text{max}},
\]
where the equality (a) follows from the rotational invariance property (Thm. 4.2), and the equality (b) follows directly from the absorption time expression (Thm. 3.1). That completes the proof. \( \square \)

The next theorem implies that the MAT of a receiver employing the FSSS does not depend on the location of the first in-phase cell. Thus, the MAT evaluation can be simplified for the case of FSSS.

**Theorem 5.3 (Simplification).** Let \( s(\pi^{N_j}, b) \) denote the spacing rule for the description \( (\pi^{N_j}, b) \) corresponding to the FSSS and the location \( 1 \leq b \leq N_{\text{unc}} \) of the first in-phase cell. Then
\[
v(s(\pi^{N_j}, 1)) = v(s(\pi^{N_j}, 2)) = \cdots = v(s(\pi^{N_j}, N_{\text{unc}})),
\]
and the MAT expression for the FSSS is equal to
\[
E \{ T_{\text{ACQ}}(\pi^{N_j}) \} = v(s(\pi^{N_j}, 1)).
\]

**Proof.** Let the step size \( N_j \) be given. Conditioned on \( B = 1 \), the set of in-phase cells is given by
\[
\mathcal{H}_{\text{hit}}(1) = \{1, 2, \ldots, N_{\text{hit}}\}
\]
\[
= \{ \pi^{N_j}(k_1), \pi^{N_j}(k_2), \ldots, \pi^{N_j}(k_{N_{\text{hit}}}) \}
\]
for some unique integers \( 1 = k_1 < k_2 < \cdots < k_{N_{\text{hit}}} \). We now transform the description \( (\pi^{N_j}, 1) \) into the spacing rule \( m \), where
\[
m_i \triangleq \begin{cases} 
  k_{i+1} - k_i - 1 & 1 \leq i \leq N_{\text{hit}} - 1 \\
  k_1 + N_{\text{unc}} - k_{N_{\text{hit}}} - 1 & i = N_{\text{hit}}.
\end{cases}
\]
For any \( j \geq 1 \), let
\[
\text{rot}_j \{ x \} \triangleq \underbrace{\text{rot}\{ \text{rot}\{ \ldots \text{rot}\{ x \} \ldots \} \}}_{j \text{ times}}
\]
denote a vector obtained from the rotations of \( x \in \mathbb{R}^{N_{\text{hit}}} \) for \( j \) times. Let
\[
\mathcal{R} \triangleq \{ m, \text{rot} \{ m \}, \text{rot}_2 \{ m \}, \ldots, \text{rot}_{N_{\text{hit}}-1} \{ m \} \}
\]
denote a set of all rotations of the spacing rule \( m \). By construction, \( s(\pi^{N_j}, 1) = m \in \mathcal{R} \).

Let any \( b \) with \( 2 \leq b \leq N_{\text{unc}} \) be given. We want to show that \( s(\pi^{N_j}, b) \in \mathcal{R} \). Consider a flow diagram with the description \( (\pi^{N_j}, b) \). Then, the set of in-phase cells is
\[
\mathcal{H}_{\text{hit}}(b) = \mathcal{H}_{\text{hit}}(1) \oplus (b-1)
\]
\[
= \{1 \oplus (k_1 - 1)N_j, 1 \oplus (k_2 - 1)N_j, \ldots, 1 \oplus (k_{N_{\text{hit}}} - 1)N_j\} \oplus (b-1)
\]
\[
= \{b \oplus (k_1 - 1)N_j, b \oplus (k_2 - 1), \ldots, b \oplus (k_{N_{\text{hit}}} - 1)\}.
\]

\( \square \)

---

\( \| \)For a set \( A \) of integers and a fixed integer \( n \), define \( A \oplus n \triangleq \{ m \oplus n \mid m \in A \} \).
where the second equality follows from the last equality of (20) and from the definition of the FSSS in (7).

Let \( x \equiv b \oplus (k_1 - 1)N_1 \) and \( y \equiv b \oplus (k_2 - 1)N_1 \) denote elements of \( \mathcal{H}_{\text{hit}}(b) \). Then, \( x \) and \( y \) are \( H_1 \)-states. For any \( k_1 < j < k_2 \), we have \( b \oplus (j - 1)N_1 \notin \mathcal{H}_{\text{hit}}(b) \) since \( k_2 < k_3 < \cdots < k_{N_{\text{hit}}} \). Thus, \( k_2 - k_1 + 1 = m_1 \) states in \( \{ b \oplus (j - 1)N_1 \mid k_1 < j < k_2 \} \) are all of the \( H_0 \)-states between the two neighboring \( H_1 \)-states \( x \) and \( y \).

A similar argument will show that, for \( 1 \leq i \leq N_{\text{hit}} \), the quantity \( m_i \) in (21) is the number of \( H_0 \)-states between two neighboring states \( b \oplus (k_i - 1)N_1 \) and \( b \oplus (k_{i+1} - 1)N_1 \). Therefore,

\[
s(\pi N_i, b) = \text{rot}_l \{ m \} \in \mathcal{R}, \quad \text{for some } l \geq 1.
\]

All spacing rules in \( \mathcal{R} \) have the same absorption time by the rotational invariance property (Thm. 4.2). Therefore, \( v(s(\pi N_1, 1)) = v(s(\pi N_2, 2)) = \cdots = v(s(\pi N_i, N_{\text{unc}})) \), which implies that the MAT expression for the FSSS is \( \mathbb{E} \{ T_{\text{ACQ}}(\pi N_i) \} = v(s(\pi N_1, 1)) \). That completes the proof. \( \Box \)

6. CONCLUSION

This paper investigates the properties of acquisition receivers that employ serial-search strategies. We begin by noting that the mean acquisition time (MAT) is a convex combination of the absorption times. We point out the difficulty in establishing the important properties of the MAT directly from the absorption time expression, obtained by a conventional method. This difficulty is then alleviated by transforming the absorption time into the spacing rule domain. The transformation offers insights into the properties of the absorption time and the MAT.

We first derive an explicit expression for the absorption time in the spacing rule domain. We then show that the absorption time is convex in \( \mathbb{R}^{N_{\text{hit}}} \), rotation invariant, and reversal invariant. We show that the minimum MAT over all possible search orders is lower bounded by the solution to an integer programming problem whose fluid approximation (or relaxation) has a convex objective function. Thus, well-known techniques in convex optimization can be used to find the explicit solution algorithmically. We also derive the upper bound on the MAT over all possible search orders. The upper bound expression is explicit and depends on the details of the signal detection procedure. We further show that the MAT of the fixed-step serial search (FSSS) does not depend on the location of the first in-phase cell. Thus, the evaluation of the MAT for the FSSS can be simplified significantly.

Throughout the paper, we deliberately represent the details, such as the fading statistic, the receiver’s architecture, and the design choice of decision variables, by a few parameters \( P_D, P_M, \tau_D, \tau_M \), and \( \tau_P \). Therefore, the results in this paper can be applied to the design and analysis of fast acquisition systems in various wideband scenarios including several fading conditions, hardware implementations, and operating environments.

APPENDIX A. NON-NEGATIVE DEFINITENESS OF THE HESSIAN MATRIX \( H \)

Lemma A.1 (Non-Negative Definite Kernel). Let \( T > 0 \) and \( -e^{-2T} < \theta < e^{-2T} \) be given. Define a kernel

\[
K(s, t) \triangleq \theta e^{s-t} + e^{-|s-t|},
\]

for \( -T \leq s, t \leq T \). Then, \( K(s, t) \) is non-negative definite on the space \([-T, T] \times [-T, T]\). That is, for any function \( f(t) \in \mathcal{L}^2[-T, T] \),

\[
\int_{-T}^{T} \int_{-T}^{T} f(s)K(s, t)f(t)dsdt \geq 0.
\]

Proof. For any \( s, t \in [-T, T] \), \( K(s, t) = K(t, s) \) and \(|K(s, t)| \leq 2 \). Thus, \( K(s, t) \) is symmetric and square-integrable (i.e., \( \int_{-T}^{T} \int_{-T}^{T} |K(s, t)|^2 dsdt < \infty \)). By [28, Thm 7.71, p. 127], \( K(s, t) \) is non-negative definite on \([-T, T] \times [-T, T] \) iff all eigenvalues of \( K(s, t) \) are positive. We will derive a complete set of eigenvalues of \( K(s, t) \) and show that they are positive.

The eigenvalues \( \lambda_i \) satisfy the following integral equation

\[
\lambda_i \varphi_i(s) = \int_{-T}^{T} K(s, t)\varphi_i(t)dt \quad -T \leq s \leq T,
\]
where $\varphi_i(t)$ are orthonormal eigenfunctions corresponding to the eigenvalues $\lambda_i$.

It can be shown that the eigenfunction satisfies the following second-order differential equation:

$$\lambda \varphi''(s) = \left[ \lambda - 2(1 - \theta) \right] \varphi(s). \quad (25)$$

When $\lambda$ is non-zero, let $\alpha \triangleq [\lambda - 2(1 - \theta)]/\lambda$ denote the normalized coefficient of $\varphi(s)$ in (25). We consider four separate cases.

1. The eigenvalue is zero: $\lambda = 0$.
   Equation (25) implies that $\varphi(s) = 0$, for $s \in [-T, T]$, which is not an eigenfunction. Therefore, this case is impossible.

2. The eigenvalue is non-zero and $\alpha > 0$. In this case, solutions to the differential equation (25) are of the form

$$\varphi(s) = A e^{\sqrt{\alpha} s} + B e^{-\sqrt{\alpha} s}. \quad (26)$$

Substituting (26) into the integral equation in (24), using the bounds on $T$ and $\theta$, and solving for $A$ and $B$, we can show after some algebra that $A = B = 0$. This case then implies that $\varphi(s) = 0$, for $s \in [-T, T]$, which is an invalid eigenfunction. Thus, there is no eigenfunction of the form in (26).

3. The eigenvalue is non-zero and $\alpha = 0$.
   Thus, solutions to (25) are of the form

$$\varphi(s) = As + B. \quad (27)$$

Substituting (27) into the integral equation in (24), using the bounds on $T$ and $\theta$, and solving for $A$ and $B$, we can show after some algebra that $A = B = 0$, which implies that no eigenfunction is of the form in (27).

4. The eigenvalue is non-zero and $\alpha < 0$.
   Thus, solutions to (25) are of the form

$$\varphi(s) = A \cos(\sqrt{|\alpha|} s) + B \sin(\sqrt{|\alpha|} s). \quad (28)$$

Substituting (28) into the integral equation in (24) and solving for $A$ and $B$, we can show after some algebra that $AB = 0$ and that the eigenvalues are given by

$$\lambda_i = \frac{2(1 - \theta)}{1 + \mu_i^2}, \quad i = 1, 2, 3, \ldots. \quad (29)$$

Here, $\mu_i$ are positive solutions to the transcendental equation

$$\left( \tan \mu T + \kappa \mu \right) \left( \tan \mu T - \frac{\kappa}{\mu} \right) = 0,$$

where $\kappa \triangleq \left( e^{-T} - e^{-\theta T} e^T \right)$. Clearly, the eigenvalues in (29) are positive.

Because all eigenvalues of $K(s, t)$ are strictly positive, $K(s, t)$ is a non-negative definite kernel. That completes the proof. □

ACKNOWLEDGMENTS

The authors wish to thank C. Caramanis, P. Falb, and T. Q.S. Quek for their helpful discussion, and I. Keliher for a careful reading of the manuscript.

**The existence of countably many eigenvalues of $K(s, t)$ follows from the theorem of Hilbert and Schmidt [29, p. 243].
